scikit-learn

Lecture 10

Dr. Colin Rundel

scikit-learn

> Scikit-learn is an open source machine learning library that supports supervised and unsupervised learning. It also provides various tools for model fitting, data preprocessing, model selection, model evaluation, and many other utilities.
>
> - Simple and efficient tools for predictive data analysis
> - Accessible to everybody, and reusable in various contexts
> - Built on NumPy, SciPy, and matplotlib
> - Open source, commercially usable - BSD license

This is one of several other “scikits” (e.g. scikit-image) which are scientific toolboxes built on top of scipy. For a more

Submodules

The `sklearn` package contains a large number of submodules which are specialized for different tasks / models,

- `sklearn.base` - Base classes and utility functions
- `sklearn.calibration` - Probability Calibration
- `sklearn.cluster` - Clustering
- `sklearn.compose` - Composite Estimators
- `sklearn.covariance` - Covariance Estimators
- `sklearn.cross_decomposition` - Cross decomposition
- `sklearn.datasets` - Datasets
- `sklearn.decomposition` - Matrix Decomposition
- `sklearn.discriminant_analysis` - Discriminant Analysis
- `sklearn.ensemble` - Ensemble Methods
- `sklearn.exceptions` - Exceptions and warnings
- `sklearn.experimental` - Experimental
- `sklearn.feature_extraction` - Feature Extraction
- `sklearn.feature_selection` - Feature Selection
- `sklearn.gaussian_process` - Gaussian Processes
- `sklearn.impute` - Impute
- `sklearn.inspection` - Inspection
- `sklearn.isotonic` - Isotonic regression
- `sklearn.kernel_approximation` - Kernel Approximation
- `sklearn.kernel_ridge` - Kernel Ridge Regression
- `sklearn.linear_model` - Linear Models
- `sklearn.manifold` - Manifold Learning
- `sklearn.metrics` - Metrics
- `sklearn.mixture` - Gaussian Mixture Models
- `sklearn.model_selection` - Model Selection
- `sklearn.multiclass` - Multiclass classification
- `sklearn.multioutput` - Multioutput regression and classification
- `sklearn.naive_bayes` - Naive Bayes
- `sklearn.neighbors` - Nearest Neighbors
- `sklearn.neural_network` - Neural network models
- `sklearn.pipeline` - Pipeline
- `sklearn.preprocessing` - Preprocessing and Normalization
- `sklearn.random_projection` - Random projection
- `sklearn.semi_supervised` - Semi-Supervised Learning
- `sklearn.svm` - Support Vector Machines
- `sklearn.tree` - Decision Trees
- `sklearn.utils` - Utilities

Model Fitting

Sample data

To begin, we will examine a simple data set on the size and weight of a number of books. The goal is to model the weight of a book using some combination of the other features in the data.

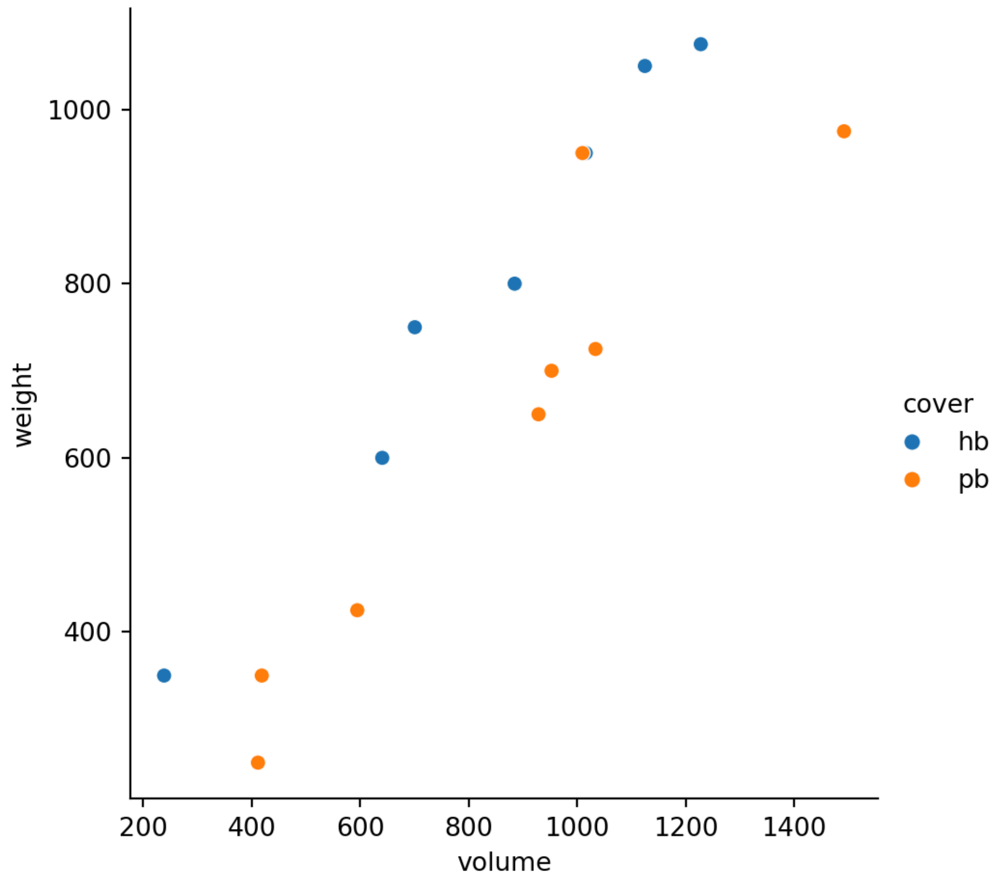
The included columns are:

- `volume` - book volumes in cubic centimeters
- `weight` - book weights in grams
- `cover` - a categorical variable with levels `"hb"` hardback, `"pb"` paperback

```
books = pd.read_csv("data/daag_books.csv");
```

```
    volume  weight cover
0      885     800    hb
1     1016     950    hb
2     1125    1050    hb
3      239     350    hb
4      701     750    hb
5      641     600    hb
6     1228    1075    hb
7      412     250    pb
8      953     700    pb
9      929     650    pb
10    1492     975    pb
11     419     350    pb
12    1010     950    pb
13     595     425    pb
14    1034     725    pb
```

```python
g = sns.relplot(data=books, x="volume", y="weight", hue="cover")
```



Linear regression

scikit-learn uses an object oriented system for implementing the various modeling approaches, the class for `LinearRegression` is part of the `linear_model` submodule.

```
from sklearn.linear_model import LinearRegression
```

Each modeling class needs to be constructed (potentially with options) and then the resulting object will provide attributes and methods.

```
lm = LinearRegression()

m = lm.fit(
  X = books[["volume"]],
  y = books.weight
)
```

```
m.coef_
```

```
array([0.70863714])
```

```
m.intercept_
```

```
np.float64(107.67931061376612)
```

Note `lm` and `m` are labels for the same underlying `LinearRegression` object,

```
lm.coef_
```

```
array([0.70863714])
```

```
lm.intercept_
```

```
np.float64(107.67931061376612)
```

A couple of considerations

When fitting a model, scikit-learn expects `X` to be a 2d array-like object (e.g. a `np.array` or `pd.DataFrame`), so it will not accept objects like a `pd.Series` or 1d `np.array`.

```python
lm.fit(
  X = books.volume,
  y = books.weight
)
```

```
ValueError: Expected a 2-dimensional container
but got <class 'pandas.core.series.Series'>
instead. Pass a DataFrame containing a single
row (i.e. single sample) or a single column
(i.e. single feature) instead.
```

```python
lm.fit(
  X = np.array(books.volume),
  y = books.weight
)
```

```
ValueError: Expected 2D array, got 1D array
instead:
array=[ 885 1016 1125  239  701  641 1228  412
953  929 1492  419 1010  595
 1034].
Reshape your data either using
array.reshape(-1, 1) if your data has a single
feature or array.reshape(1, -1) if it contains
a single sample.
```

```python
lm.fit(
  X = np.array(books.volume).reshape(-1,1),
  y = books.weight
)
```

Model parameters

Depending on the model being used, there will be a number of parameters that can be configured when creating the model object or via the `set_params()` method.

```
lm.get_params()
```

```
{'copy_X': True, 'fit_intercept': True, 'n_jobs': None, 'positive': False}
```

```
lm.set_params(fit_intercept = False)
```

```
▾ LinearRegression
LinearRegression(fit_intercept=False)
```

```
lm = lm.fit(X = books[["volume"]], y = books.weight)
lm.intercept_
```

```
0.0
```

```
lm.coef_
```

```
array([0.81932487])
```

Model prediction

Once the model coefficients have been fit, it is possible to predict from the model via the `predict()` method, this method requires a matrix-like `X` as input and in the case of `LinearRegression` returns an array of predicted y values.

```
lm.predict(X = books[["volume"]])
```

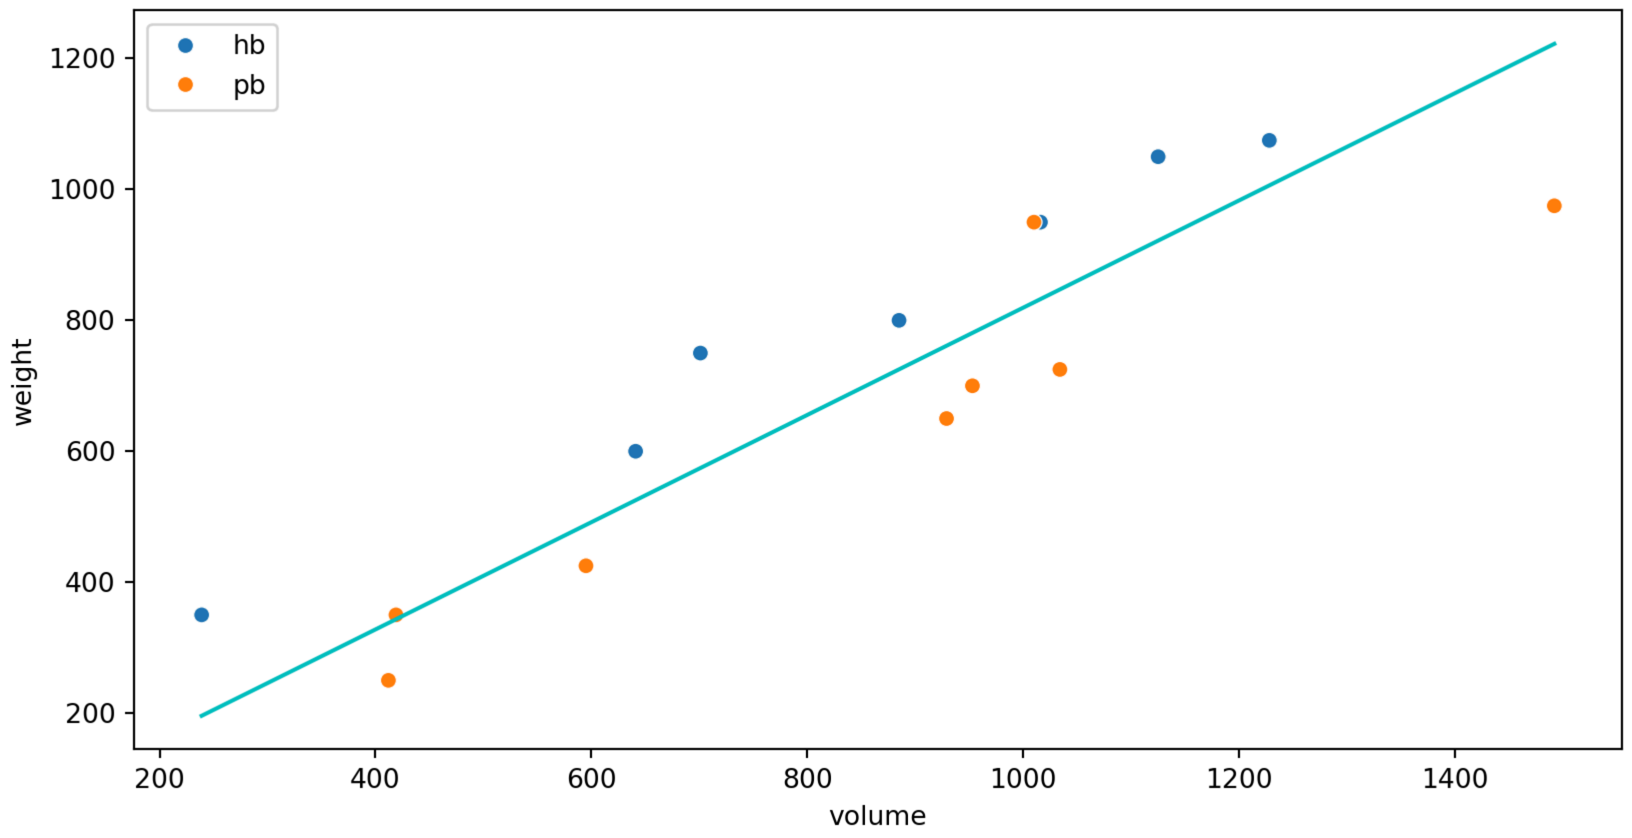
```
array([ 725.10251417,  832.43407276,  921.74048411,  195.81864507,
        574.34673721,  525.18724472, 1006.13094621,  337.5618484 ,
        780.81660565,  761.15280865, 1222.43271315,  343.29712253,
        827.51812351,  487.49830048,  847.1819205 ])
```

```
books = books.assign(
  weight_lm_pred = lambda x: lm.predict(X = x[["volume"]])
)
books
```

	volume	weight	cover	weight_lm_pred
0	885	800	hb	725.102514
1	1016	950	hb	832.434073
2	1125	1050	hb	921.740484
3	239	350	hb	195.818645
4	701	750	hb	574.346737
5	641	600	hb	525.187245
6	1228	1075	hb	1006.130946

```
7      412      250    pb       337.561848
8      953      700    pb       780.816606
9      929      650    pb       761.152809
10    1492      975    pb      1222.432713
11     419      350    pb       343.297123
12    1010      950    pb       827.518124
13     595      425    pb       487.498300
```

```
plt.figure()
sns.scatterplot(data=books, x="volume", y="weight", hue="cover")
sns.lineplot(data=books, x="volume", y="weight_lm_pred", color="c")
plt.show()
```

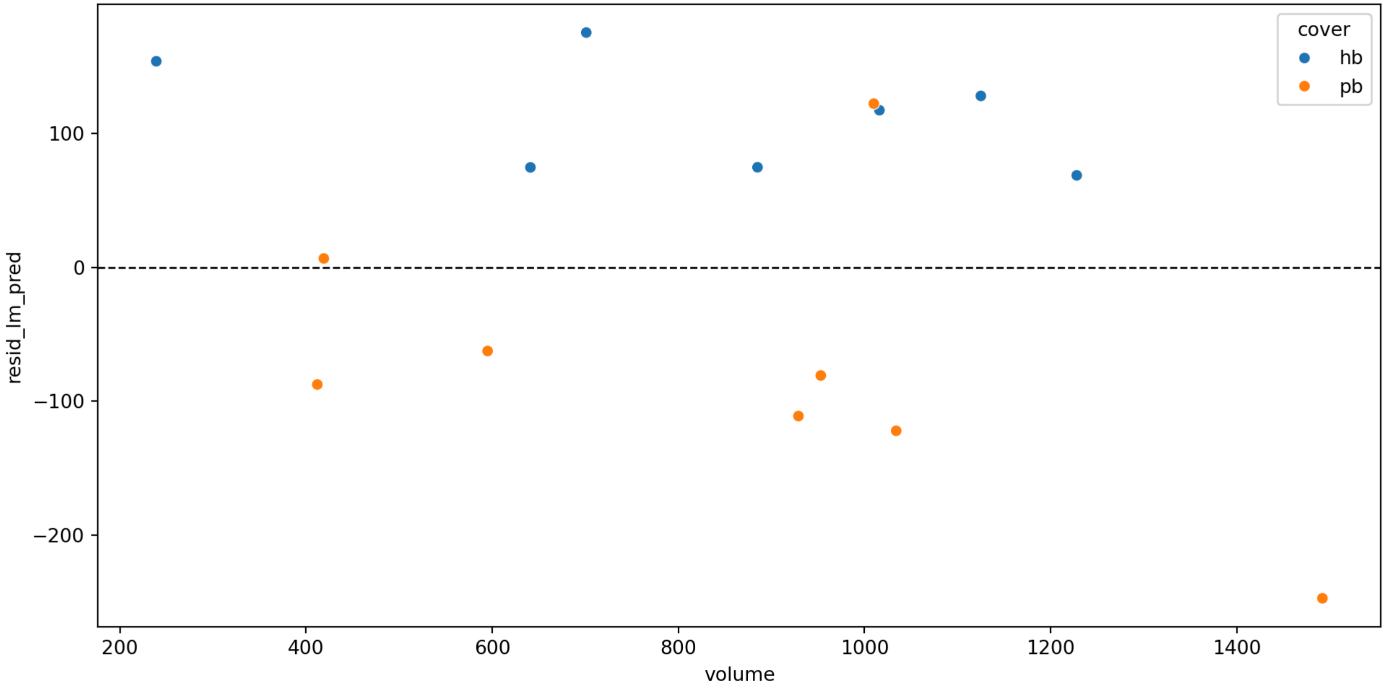


Residuals?

There is no built in functionality for calculating residuals, so this needs to be done by hand.

```
books["resid_lm_pred"] = books["weight"] - books["weight_lm_pred"]
```

```
plt.figure(layout="constrained")
ax = sns.scatterplot(data=books, x="volume", y="resid_lm_pred", hue="cover")
ax.axhline(c="k", ls="--", lw=1)
plt.show()
```



Categorical variables?

Scikit-learn expects that the model matrix be numeric before fitting,

```
lm = lm.fit(
  X = books[["volume", "cover"]],
  y = books.weight
)
```

```
ValueError: could not convert string to float: 'hb'
```

the solution here is to dummy code the categorical variables - this can be done with pandas via `pd.get_dummies()` or with a scikit-learn preprocessor.

```
pd.get_dummies(books[["volume", "cover"]])
```

```
   volume  cover_hb  cover_pb
0     885      True     False
1    1016      True     False
2    1125      True     False
3     239      True     False
4     701      True     False
5     641      True     False
6    1228      True     False
7     412     False      True
8     953     False      True
9     929     False      True
```

```
10    1492    False    True
11     419    False    True
12    1010    False    True
13     595    False    True
```

Dummy coded model

```
lm = LinearRegression().fit(
  X = pd.get_dummies(books[["volume", "cover"]]),
  y = books.weight
)
```

```
lm.intercept_
```

```
np.float64(105.93920788192202)
```

```
lm.coef_
```

```
array([  0.71795374,  92.02363569, -92.02363569])
```

Do the above results look reasonable? What went wrong?

Quick comparison with R

```r
d = read.csv('data/daag_books.csv')
d['cover_hb'] = ifelse(d$cover == "hb", 1, 0)
d['cover_pb'] = ifelse(d$cover == "pb", 1, 0)
lm = lm(weight~volume+cover_hb+cover_pb, data=d)
summary(lm)
```

```
Call:
lm(formula = weight ~ volume + cover_hb + cover_pb, data = d)

Residuals:
    Min      1Q  Median      3Q     Max 
-110.10  -32.32  -16.10   28.93  210.95 

Coefficients: (1 not defined because of singularities)
             Estimate Std. Error t value Pr(>|t|)    
(Intercept)  13.91557   59.45408   0.234 0.818887    
volume        0.71795    0.06153  11.669  6.6e-08 ***
cover_hb    184.04727   40.49420   4.545 0.000672 ***
cover_pb           NA         NA      NA       NA    
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 78.2 on 12 degrees of freedom
```

Avoiding co-linearity

```
lm1 = LinearRegression(
  fit_intercept = False
).fit(
  X = pd.get_dummies(books[["volume",
  y = books.weight
)
```

```
lm1.intercept_
```

```
0.0
```

```
lm1.coef_
```

```
array([  0.71795374, 197.96284357,
13.91557219])
```

```
lm1.feature_names_in_
```

```
array(['volume', 'cover_hb', 'cover_pb'],
dtype=object)
```

```
lm2 = LinearRegression(
  fit_intercept = True
).fit(
  X = pd.get_dummies(
    books[["volume", "cover"]],
    drop_first=True
  ),
  y = books.weight
)
```

```
lm2.intercept_
```

```
np.float64(197.96284357271747)
```

```
lm2.coef_
```

```
array([   0.71795374, -184.04727138])
```

```
lm2.feature_names_in_
```

```
array(['volume', 'cover_pb'],
dtype=object)
```

Preprocessors

Preprocessors

These are a collection of transformer classes present in the `sklearn.preprocessing` submodule that are designed to help with the preparation of raw feature data into quantities more suitable for downstream modeling tools.

Like the modeling classes, they have an object oriented design that shares a common interface (methods and attributes) for bringing in data, transforming it, and returning it.

OneHotEncoder

For dummy coding we can use the `OneHotEncoder` preprocessor, the default is to use one hot encoding but standard dummy coding can be achieved via the `drop` parameter.

```
from sklearn.preprocessing import OneHotEncoder
```

```python
enc = OneHotEncoder(sparse_output=False)
enc.fit(X = books[["cover"]])
```

```
OneHotEncoder
OneHotEncoder(sparse_output=False)
```

```python
enc.transform(X = books[["cover"]])
```

```
array([[1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.]])
```

```python
enc = OneHotEncoder(sparse_output=False, dro
enc.fit_transform(X = books[["cover"]])
```

```
array([[0.],
       [0.],
       [0.],
       [0.],
       [0.],
       [0.],
       [0.],
       [1.],
       [1.],
       [1.],
       [1.],
       [1.],
       [1.],
       [1.],
       [1.]])
```

Other useful bits

```
enc.get_feature_names_out()
```

```
array(['cover_hb', 'cover_pb'], dtype=object)
```

```
f = enc.transform(X = books[["cover"]])
f
```

```
array([[1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [1., 0.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.],
       [0., 1.]])
```

```
enc.inverse_transform(f)
```

```
array([['hb'],
       ['hb'],
       ['hb'],
       ['hb'],
       ['hb'],
       ['hb'],
       ['hb'],
       ['pb'],
       ['pb'],
       ['pb'],
       ['pb'],
       ['pb'],
       ['pb'],
       ['pb'],
       ['pb']], dtype=object)
```

A cautionary note

Unlike `pd.get_dummies()` it is not safe to use `OneHotEncoder` with both numerical and categorical features, as the former will also be transformed.

```python
enc = OneHotEncoder(sparse_output=False)
X = enc.fit_transform(X = books[["volume", "cover"]])
pd.DataFrame(data=X, columns = enc.get_feature_names_out())
```

```
    volume_239  volume_412  volume_419  ...  volume_1492  cover_hb  cover_pb
0          0.0         0.0         0.0  ...          0.0       1.0       0.0
1          0.0         0.0         0.0  ...          0.0       1.0       0.0
2          0.0         0.0         0.0  ...          0.0       1.0       0.0
3          1.0         0.0         0.0  ...          0.0       1.0       0.0
4          0.0         0.0         0.0  ...          0.0       1.0       0.0
5          0.0         0.0         0.0  ...          0.0       1.0       0.0
6          0.0         0.0         0.0  ...          0.0       1.0       0.0
7          0.0         1.0         0.0  ...          0.0       0.0       1.0
8          0.0         0.0         0.0  ...          0.0       0.0       1.0
9          0.0         0.0         0.0  ...          0.0       0.0       1.0
10         0.0         0.0         0.0  ...          1.0       0.0       1.0
11         0.0         0.0         1.0  ...          0.0       0.0       1.0
12         0.0         0.0         0.0  ...          0.0       0.0       1.0
13         0.0         0.0         0.0  ...          0.0       0.0       1.0
14         0.0         0.0         0.0  ...          0.0       0.0       1.0
```

Putting it together

```
cover = OneHotEncoder(
  sparse_output=False
).fit_transform(
  books[["cover"]]
)
X = np.c_[books.volume, cover]

lm2 = LinearRegression(
  fit_intercept=False
).fit(
  X = X,
  y = books.weight
)

lm2.coef_
```

```
array([  0.71795374, 197.96284357,
13.91557219])
```

```
books["weight_lm2_pred"] = lm2.predict(X=X)
books.drop(
  ["weight_lm_pred", "resid_lm_pred"],
  axis=1
)
```

	volume	weight	cover	weight_lm2_pred

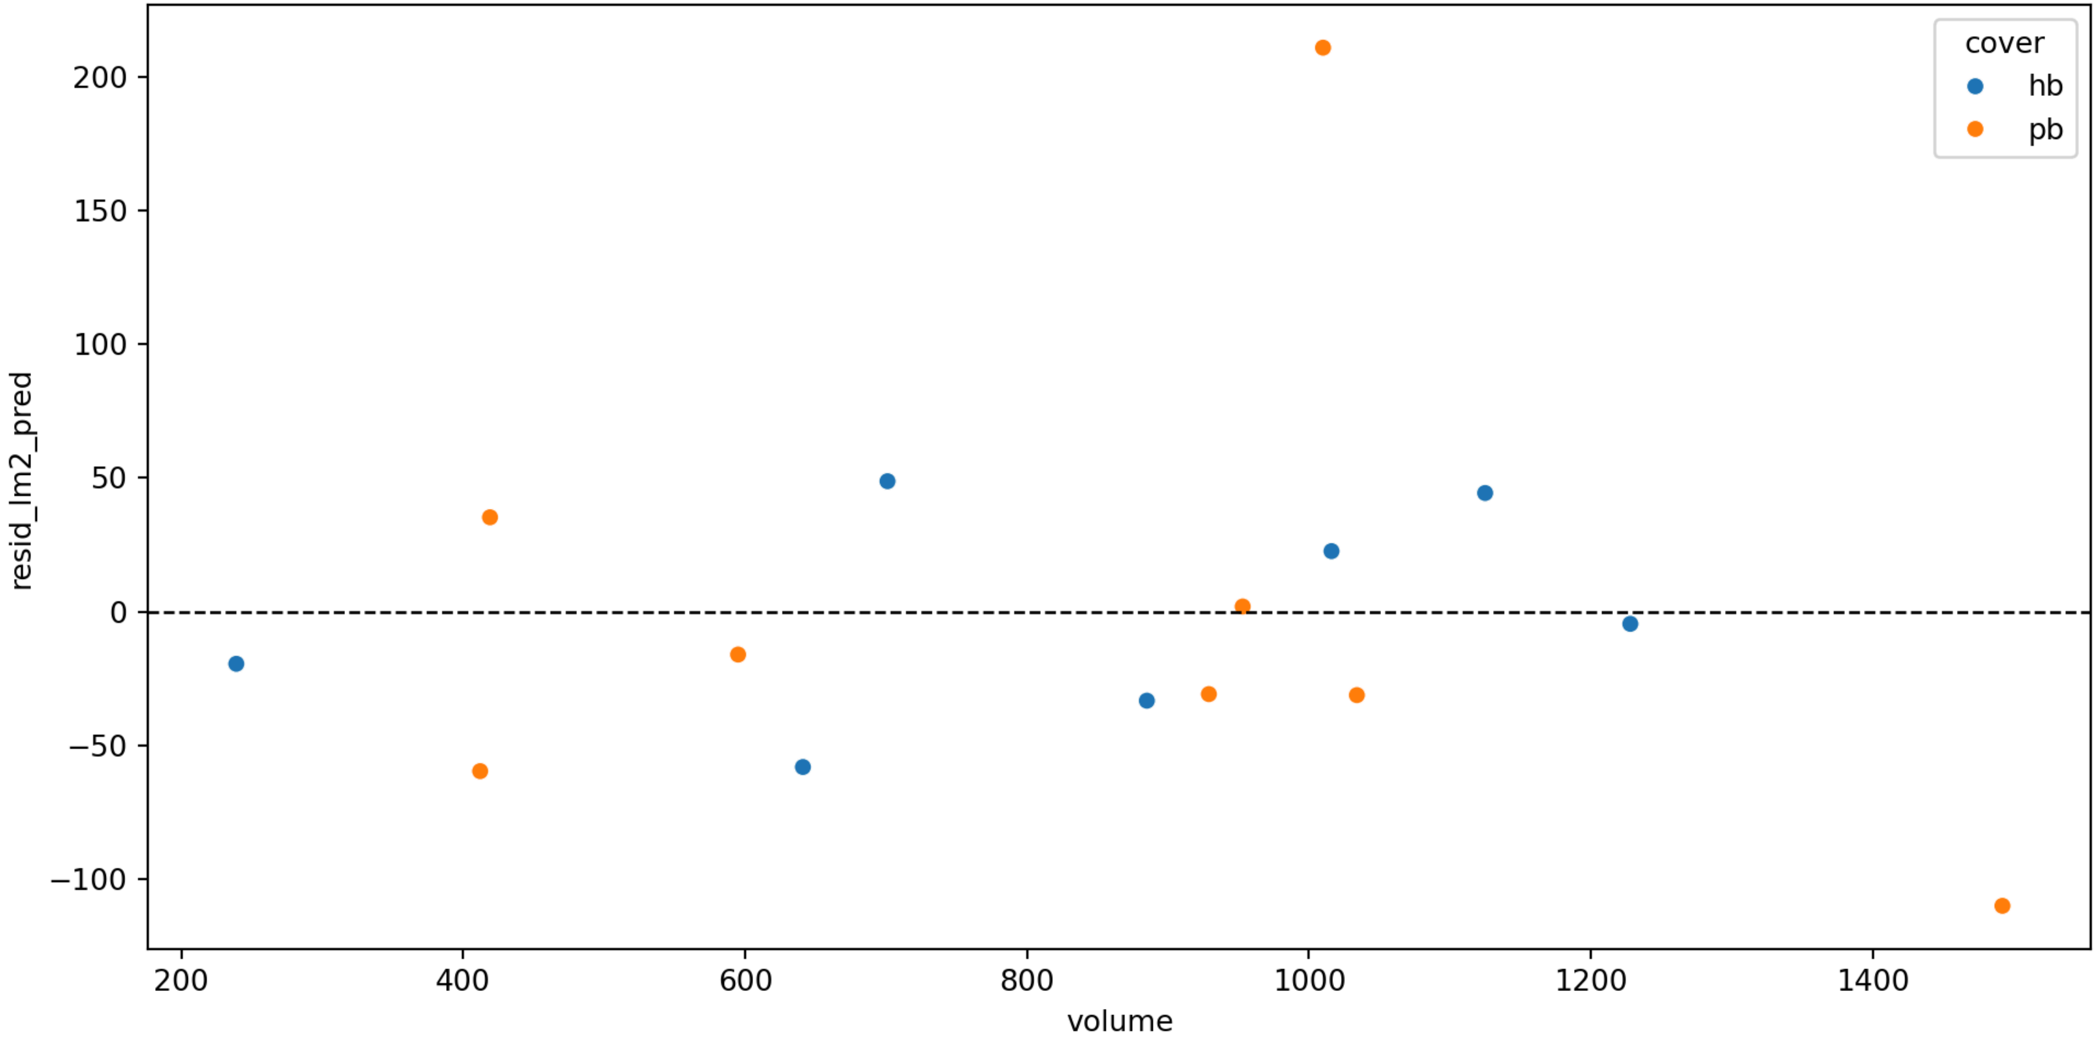
Model residuals



Model performance

Scikit-learn comes with a number of builtin functions for measuring model performance in the `sklearn.metrics` submodule - these are generally just functions that take the vectors `y_true` and `y_pred` and return a scalar score.

```
import sklearn.metrics as metrics
```

```
metrics.r2_score(books.weight, books.weight_
```

```
0.7800969547785039
```

```
metrics.mean_squared_error(
  books.weight, books.weight_lm_pred
)
```

```
14833.682083774476
```

```
metrics.root_mean_squared_error(
  books.weight, books.weight_lm_pred
)
```

```
121.79360444528471
```

```
metrics.r2_score(books.weight, books.weight_
```

```

```

Exercise 1

Create and fit a model for the `books` data that includes an interaction effect between `volume` and `cover`.

You will need to do this manually with `pd.getdummies()` and some additional data munging.

The data can be read into pandas with,

```
books = pd.read_csv(
  "https://sta663-sp25.github.io/slides/data/daag_books.csv"
)
```

Other transformers

Polynomial regression

We will now look at another flavor of regression model, that involves preprocessing and a hyperparameter - namely polynomial regression.

```
df = pd.read_csv("data/gp.csv")
sns.relplot(data=df, x="x", y="y")
```

x

By hand

It is certainly possible to construct the necessary model matrix by hand (or even use a function to automate the process), but this is less then desirable generally - particularly if we want to do anything fancy (e.g. cross validation)

```
X = np.c_[
    np.ones(df.shape[0]),
    df.x,
    df.x**2,
    df.x**3
]

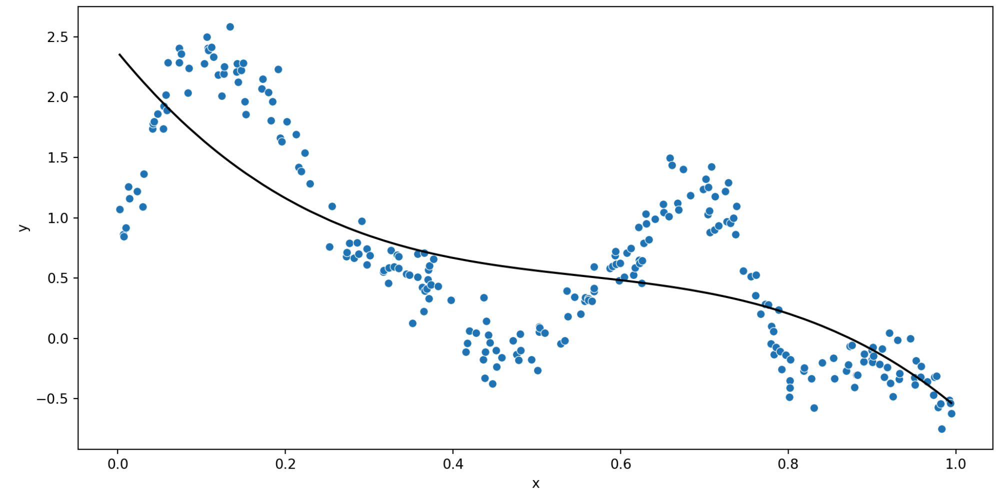
plm = LinearRegression(
  fit_intercept = False
).fit(
  X=X, y=df.y
)

plm.coef_
```

```
array([ 2.36985684, -8.49429068,
13.95066369, -8.39215284])
```

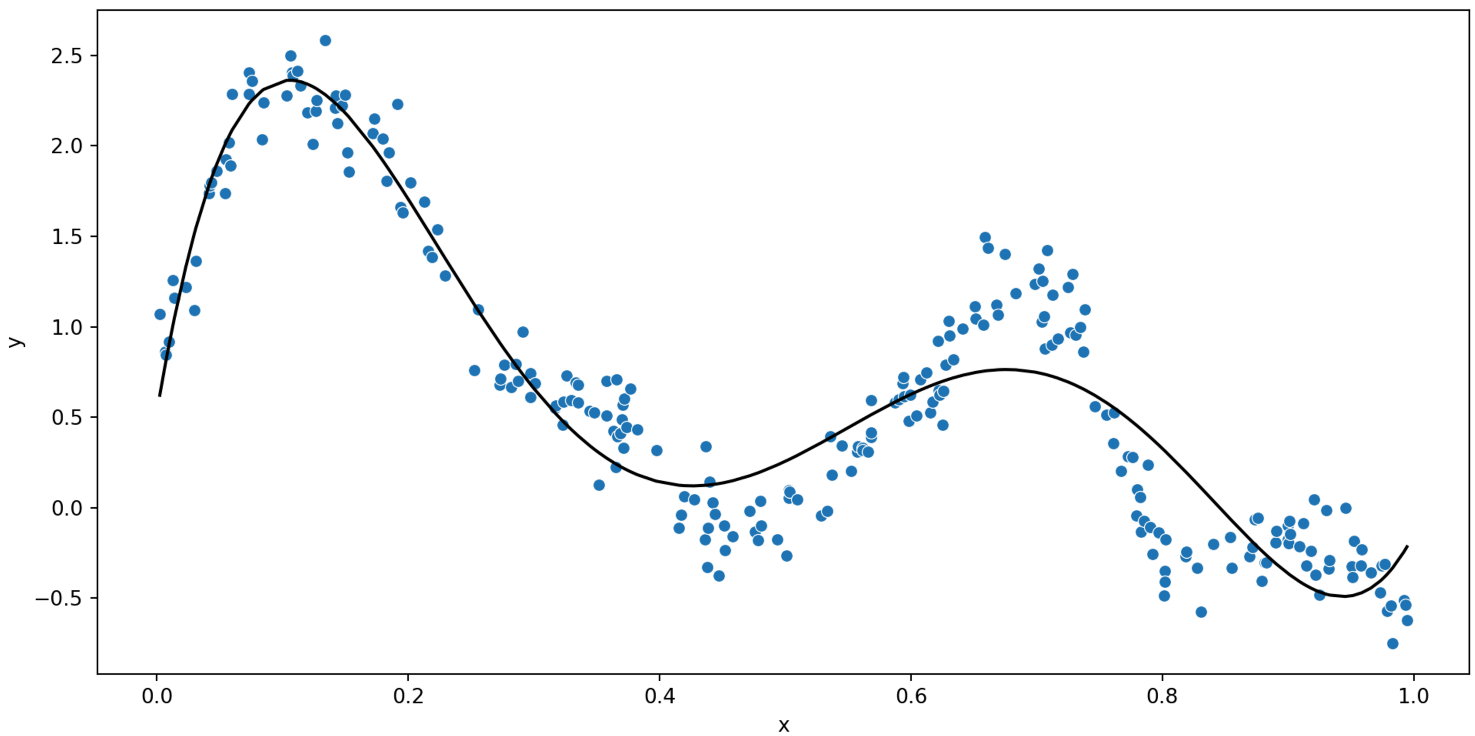
```
df["y_pred"] = plm.predict(X=X)

plt.figure(layout="constrained")
sns.scatterplot(data=df, x="x", y="y")
sns.lineplot(data=df, x="x", y="y_pred
plt.show()
```



```python
X = np.c_[
    np.ones(df.shape[0]), df.x,
    df.x**2, df.x**3,
    df.x**4, df.x**5
]

plm = LinearRegression(
  fit_intercept = False
).fit(
  X=X, y=df.y
)
df["y_pred"] = plm.predict(X=X)
```



PolynomialFeatures

This is another transformer class from `sklearn.preprocessing` that simplifies the process of constructing polynormial features for your model matrix. Usage is similar to that of `OneHotEncoder`.

```
from sklearn.preprocessing import PolynomialFeatures
X = np.array(range(6)).reshape(-1,1)
```

```
pf = PolynomialFeatures(degree=3)
pf = pf.fit(X)
pf.transform(X)
```

```
array([[  1.,   0.,   0.,   0.],
       [  1.,   1.,   1.,   1.],
       [  1.,   2.,   4.,   8.],
       [  1.,   3.,   9.,  27.],
       [  1.,   4.,  16.,  64.],
       [  1.,   5.,  25., 125.]])
```

```
pf.get_feature_names_out()
```

```
array(['1', 'x0', 'x0^2', 'x0^3'],
dtype=object)
```

```
pf = PolynomialFeatures(
  degree=2, include_bias=False
)
pf.fit_transform(X)
```

```
array([[ 0.,  0.],
       [ 1.,  1.],
       [ 2.,  4.],
       [ 3.,  9.],
       [ 4., 16.],
       [ 5., 25.]])
```

```
pf.get_feature_names_out()
```

```
array(['x0', 'x0^2'], dtype=object)
```

Interactions

If the feature matrix `X` has more than one column than `PolynomialFeatures` transformer will include interaction terms with total degree up to `degree`.

```
X.reshape(-1, 2)
```

```
array([[0, 1],
       [2, 3],
       [4, 5]])
```

```
pf = PolynomialFeatures(
  degree=2, include_bias=False
)
pf.fit_transform(
  X.reshape(-1, 2)
)
```

```
array([[ 0.,  1.,  0.,  0.,  1.],
       [ 2.,  3.,  4.,  6.,  9.],
       [ 4.,  5., 16., 20., 25.]])
```

```
pf.get_feature_names_out()
```

```
array(['x0', 'x1', 'x0^2', 'x0 x1', 'x1^2'],
dtype=object)
```

```
X.reshape(-1, 3)
```

```
array([[0, 1, 2],
       [3, 4, 5]])
```

```
pf = PolynomialFeatures(
  degree=2, include_bias=False
)
pf.fit_transform(
  X.reshape(-1, 3)
)
```

```
array([[ 0.,  1.,  2.,  0.,  0.,  0.,  1.,  2.,
4.],
       [ 3.,  4.,  5.,  9., 12., 15., 16., 20.,
25.]])
```

```
pf.get_feature_names_out()
```

```
array(['x0', 'x1', 'x2', 'x0^2', 'x0 x1', 'x0
x2', 'x1^2', 'x1 x2',
       'x2^2'], dtype=object)
```

Modeling with PolynomialFeatures

```python
def poly_model(X, y, degree):
  X  = PolynomialFeatures(
    degree=degree, include_bias=False
  ).fit_transform(
    X=X
  )
  y_pred = LinearRegression(
  ).fit(
    X=X, y=y
  ).predict(
    X
  )
  return metrics.root_mean_squared_error(y,
```

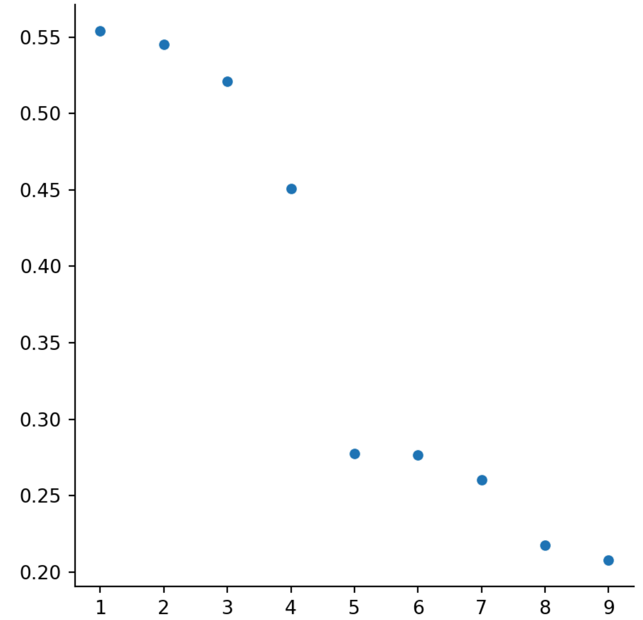
```python
poly_model(X = df[["x"]], y = df.y, degree =
```

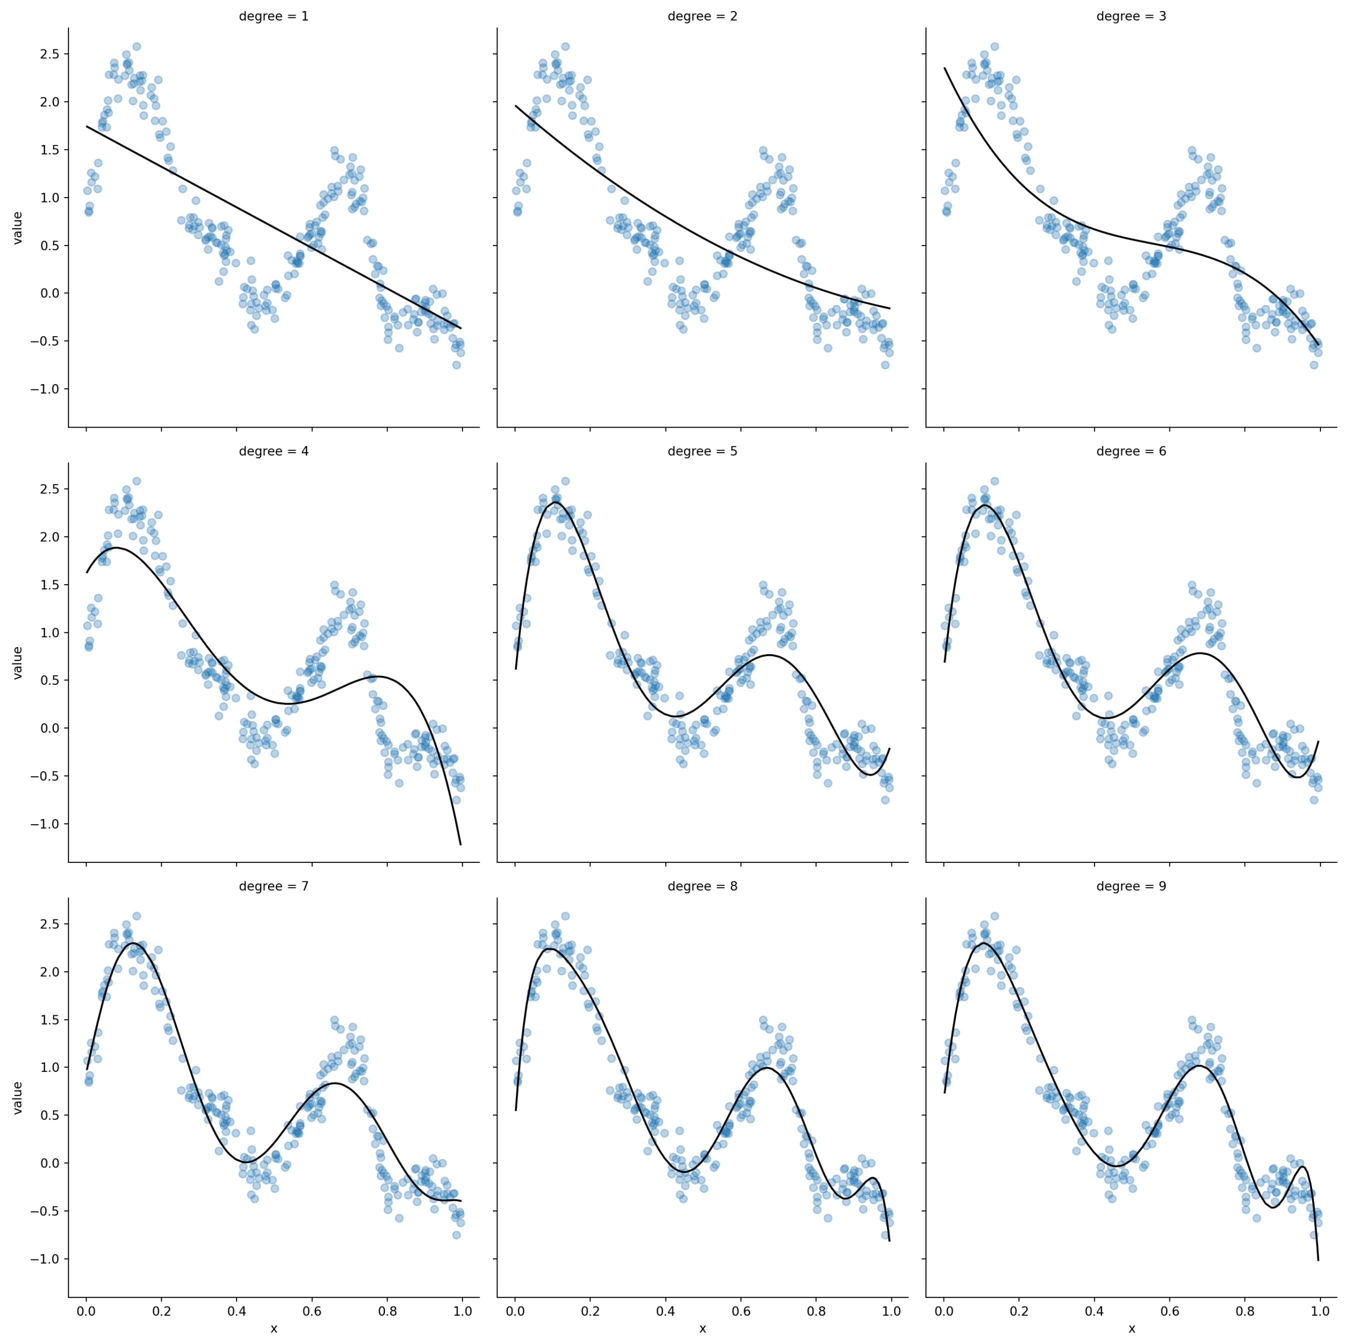
```
0.5449418707295371
```

```python
poly_model(X = df[["x"]], y = df.y, degree =
```

```
0.5208157900621085
```

```python
degrees = range(1,10)
rmses = [
  poly_model(X=df[["x"]], y=df.y, degree=d)
  for d in degrees
]
g = sns.relplot(x=degrees, y=rmses)
```





degree = 1
degree = 2
degree = 3
degree = 4
degree = 5
degree = 6
degree = 7
degree = 8
degree = 9
value
x

Pipelines

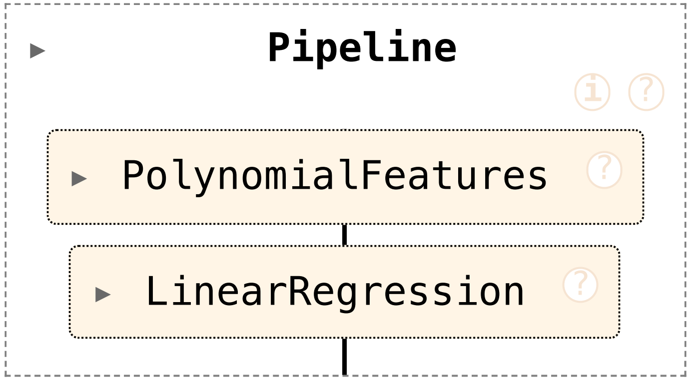
Pipelines

You may have noticed that `PolynomialFeatures` takes a model matrix as input and returns a new model matrix as output which is then used as the input for `LinearRegression`. This is not an accident, and by structuring the library in this way sklearn is designed to enable the connection of these steps together, into what sklearn calls a *pipeline*.

```python
from sklearn.pipeline import make_pipeline

p = make_pipeline(
  PolynomialFeatures(degree=4),
  LinearRegression()
)
```

```python
p
```



Using Pipelines

Once constructed, this object can be used just like our previous `LinearRegression` model (i.e. fit to our data and then used for prediction)

```
p = p.fit(X = df[["x"]], y = df.y)
p.predict(X = df[["x"]])
```

```
array([ 1.6295693 ,  1.65734929,  1.6610466 ,  1.67779767,  1.69667491,

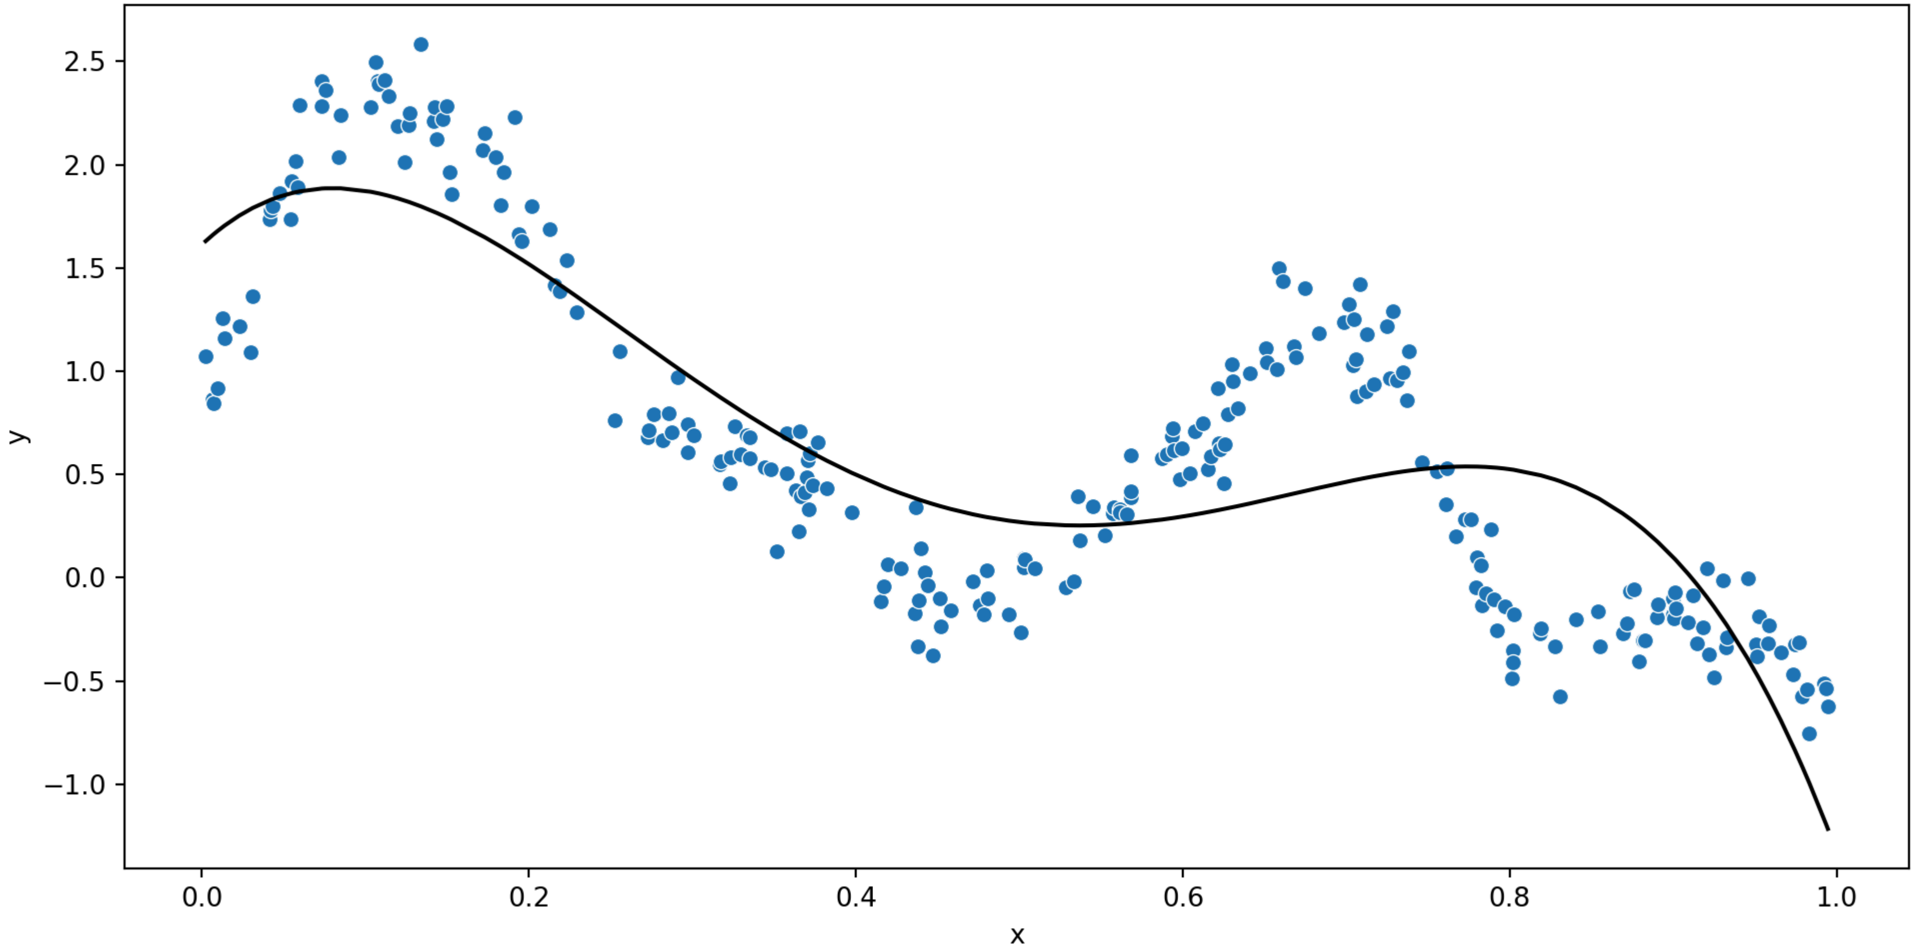
        0.84171166,  0.82875003,  0.8085086 ,  0.79166069,  0.78167248,
```

```
plt.figure(layout="constrained")
sns.scatterplot(data=df, x="x", y="y")
sns.lineplot(x=df.x, y=p.predict(X = df[["x"]]), color="k")
plt.show()
```



Model coefficients (or other attributes)

The attributes of pipeline steps are not directly accessible, but can be accessed via the `steps` or `named_steps` attributes,

```
p.coef_
```

```
AttributeError: 'Pipeline' object has no attribute 'coef_'
```

```
p.steps
```

```
[('polynomialfeatures', PolynomialFeatures(degree=4)), ('linearregression',
LinearRegression())]
```

```
p.steps[1][1].coef_
```

```
array([  0.        ,   7.39051417, -57.67175293, 102.72227443,
       -55.38181361])
```

```
p.named_steps["linearregression"].intercept_
```

```
np.float64(1.6136636604768198)
```

Other useful bits

```
p.steps[0][1].get_feature_names_out()
```

```
array(['1', 'x', 'x^2', 'x^3', 'x^4'], dtype=object)
```

```
p.steps[1][1].get_params()
```

```
{'copy_X': True, 'fit_intercept': True, 'n_jobs': None, 'positive': False}
```

Anyone notice a problem?

```
p.steps[1][1].rank_
```

```
4
```

```
p.steps[1][1].n_features_in_
```

```
5
```

What about step parameters?

By accessing each step we can adjust their parameters (via `set_params()`),

```
p.named_steps["linearregression"].get_params()
```

```
{'copy_X': True, 'fit_intercept': True, 'n_jobs': None, 'positive': False}
```

```
p.named_steps["linearregression"].set_params
  fit_intercept=False
)
```

```
▾ LinearRegression
LinearRegression(fit_intercept=False)
```

```
p.fit(X = df[["x"]], y = df.y)
```

```
▸ Pipeline
  ▸ PolynomialFeatures
  ▸ LinearRegression
```

```
p.named_steps["linearregression"].intercept_
```

```
0.0
```

```
p.named_steps["linearregression"].coef_
```

```
array([  1.61366366,   7.39051417,

       -55.38181361])
```

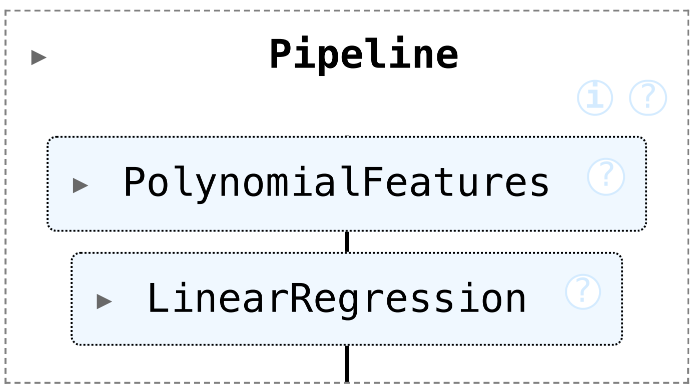
Pipeline parameter names

These parameters can also be directly accessed at the pipeline level, names are constructed as step name + __ + parameter name:

```python
p.get_params()
```

```
{'memory': None, 'steps': [('polynomialfeatures', PolynomialFeatures(degree=4)),
('linearregression', LinearRegression(fit_intercept=False))], 'transform_input': None,
'verbose': False, 'polynomialfeatures': PolynomialFeatures(degree=4), 'linearregression':
LinearRegression(fit_intercept=False), 'polynomialfeatures__degree': 4,
'polynomialfeatures__include_bias': True, 'polynomialfeatures__interaction_only': False,
'polynomialfeatures__order': 'C', 'linearregression__copy_X': True,
'linearregression__fit_intercept': False, 'linearregression__n_jobs': None,
'linearregression__positive': False}
```

```python
p.set_params(
  linearregression__fit_intercept=True,
  polynomialfeatures__include_bias=False
)
```



```
p.fit(X = df[["x"]], y = df.y)
```

```
Pipeline
  PolynomialFeatures
  LinearRegression
```

```
p.named_steps["polynomialfeatures"].get_feature_names_out()
```

```
array(['x', 'x^2', 'x^3', 'x^4'], dtype=object)
```

```
p.named_steps["linearregression"].intercept_
```

```
np.float64(1.6136636604768482)
```

```
p.named_steps["linearregression"].coef_
```

```
array([  7.39051417, -57.67175293, 102.72227443, -55.38181361])
```

Column Transformers

Column Transformers

Are a tool for selectively applying transformer(s) to column(s) of an array or DataFrame, they function in a way that is similar to a pipeline and similarly have a `make_` helper function.

```
from sklearn.compose import make_column_transformer
from sklearn.preprocessing import StandardScaler, OneHotEncoder
```

```python
ct = make_column_transformer(
  (StandardScaler(), ["volume"]),
  (OneHotEncoder(), ["cover"]),
).fit(
  books
)
```

```python
ct.get_feature_names_out()
```

```
array(['standardscaler__volume',
'onehotencoder__cover_hb',
       'onehotencoder__cover_pb'],
dtype=object)
```

```python
ct.transform(books)
```

```
array([[ 0.12100717,  1.        ,  0.        ],
       [ 0.51996539,  1.        ,  0.        ],
       [ 0.85192299,  1.        ,  0.        ],
       [-1.84637457,  1.        ,  0.        ],
       [-0.43936162,  1.        ,  0.        ],
       [-0.62209057,  1.        ,  0.        ],
       [ 1.1656077 ,  1.        ,  0.        ],
       [-1.31950608,  0.        ,  1.        ],
       [ 0.32809999,  0.        ,  1.        ],
       [ 0.25500841,  0.        ,  1.        ],
       [ 1.9696151 ,  0.        ,  1.        ],
       [-1.2981877 ,  0.        ,  1.        ],
       [ 0.5016925 ,  0.        ,  1.        ],
       [-0.76218277,  0.        ,  1.        ],
       [ 0.57478408,  0.        ,  1.        
]])
```

Keeping or dropping other columns

One addition important argument is `remainder` which determines what happens to unspecified columns. The default is `"drop"` which is why `weight` was removed, the alternative is `"passthrough"` which retains untransformed columns.

```
ct = make_column_transformer(
  (StandardScaler(), ["volume"]),
  (OneHotEncoder(), ["cover"]),
  remainder = "passthrough"
).fit(
  books
)
```

```
ct.get_feature_names_out()
```

```
array(['standardscaler__volume', 'onehotencoder__cover_hb',
       'onehotencoder__cover_pb', 'remainder__weight'], dtype=object)
```

```
ct.transform(books)
```

```
array([[ 1.21007174e-01,  1.00000000e+00,  0.00000000e+00,
         8.00000000e+02],
       [ 5.19965391e-01,  1.00000000e+00,  0.00000000e+00,
         9.50000000e+02],
       [ 8.51922992e-01,  1.00000000e+00,  0.00000000e+00,
         1.05000000e+03],
       [-1.84637457e+00,  1.00000000e+00,  0.00000000e+00,
         3.50000000e+02],
       [-4.39361619e-01,  1.00000000e+00,  0.00000000e+00,
         7.50000000e+02],
       [-6.22090574e-01,  1.00000000e+00,  0.00000000e+00,
         6.00000000e+02],
```

```
[ 1.16560770e+00,  1.00000000e+00,  0.00000000e+00,
  1.07500000e+03],
[-1.31950608e+00,  0.00000000e+00,  1.00000000e+00,
  2.50000000e+02],
[ 3.28099989e-01,  0.00000000e+00,  1.00000000e+00,
```

Column selection

One lingering issue with the above approach is that we've had to hard code the column names (or use indexes). Often we want to select columns based on their dtype (e.g. categorical vs numerical) this can be done via pandas or sklearn,

```
from sklearn.compose import make_column_selector
```

```
ct = make_column_transformer(
  ( StandardScaler(),
    make_column_selector(
      dtype_include=np.number
    )
  ),
  ( OneHotEncoder(),
    make_column_selector(
      dtype_include=[object, bool]
    )
  )
)
```

```
ct = make_column_transformer(
  ( StandardScaler(),
    books.select_dtypes(
      include=['number']
    ).columns
  ),
  ( OneHotEncoder(),
    books.select_dtypes(
      include=['object']
    ).columns
  )
)
```

```
ct.fit_transform(books)
```

```
array([[ 0.12100717,  0.35935849,  1.
,  0.        ],
       [ 0.51996539,  0.93689893,  1.
,  0.        ],
       [ 0.85192299,  1.32192589,  1.
,  0.        ],
       [-1.84637457, -1.37326282,  1.
,  0.        ],
       [-0.43936162,  0.16684502,  1.
,  0.        ],
       [-0.62209057, -0.41069542,  1.
,  0.        ],
       [ 1.1656077 ,  1.41818263,  1.
,  0.        ],
       [-1.31950608, -1.75828978,  0.
```

```
ct.get_feature_names_out()
```

```
array(['standardscaler__volume',
'standardscaler__weight',
       'onehotencoder__cover_hb',
'onehotencoder__cover_pb'], dtype=object)
```

```
ct.fit_transform(books)
```

```
array([[ 0.12100717,  0.35935849,  1.
